All secondary distribution boxes have residual current circuit breakers

Overview

The equipment within these boxes varies: primary distribution cabinets usually contain isolating switches, circuit breakers, and residual current devices (RCDs); secondary cabinets contain large three-phase circuit breakers; tertiary cabinets contain single-phase. The equipment within these boxes varies: primary distribution cabinets usually contain isolating switches, circuit breakers, and residual current devices (RCDs); secondary cabinets contain large three-phase circuit breakers; tertiary cabinets contain single-phase. A residual-current device (RCD), residual-current circuit breaker (RCCB) or ground fault circuit interrupter (GFCI) is an electrical safety device, more specifically a form of Earth-leakage circuit breaker, that interrupts an electrical circuit when the current passing through line and neutral. One bay unit includes circuit breaker, disconnect(s), measuring transformers and the local control and interface cabinet in one transportation unit. The unit has been factory-assembled and tested, offering standard connection points to protection and remote control circuits. Protect human life and vital equipment from dangerous current with a residual current circuit breaker to rapidly disconnect power when faults. The residual current device (RCD) or residual current circuit breaker (RCCB) enables the rapid disconnection of electricity, thereby avoiding prolonged and potentially serious shocks. From there, the power is distributed through the breakers to secondary.
