Does the optical splitter affect IP address

Overview

Understanding splitter ratios and insertion loss is fundamental to building a reliable fibre optic network.

Key Takeaways

No, an optical splitter does not split or alter IP addresses; it only divides the optical signal among multiple fibers. Function of an Optical Splitter

An optical splitter is a passive device used in fiber-optic networks, particularly in Passive Optical Networks (PON), to divide a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' premises . It operates purely at the physical layer, redistributing light signals without any processing of the data content, including IP addresses . Splitters can have various configurations, such as 1x2, 1x4, 1x8, or even 1x64, which indicate how many output fibers the input signal is divided into . The split ratio determines how the optical power is distributed among the outputs, but it does not affect the logical addressing or routing of the data.

IP Address Handling

IP addresses exist at the network layer of the OSI model, which is several layers above the physical layer where optical splitters operate. The splitter simply passes the optical signal along to multiple endpoints; the IP address is preserved intact in the data packets. Routing, switching, and IP assignment are handled by network devices such as routers, switches, or the OLT itself, not by the splitter .

Summary

- Optical splitters: Divide light signals among multiple fibers; passive; no power required; operate at the physical layer .
- IP addresses: Managed at the network layer; unaffected by splitters.
- Implication: Multiple users can share a single fiber from the OLT, but each ONT still receives data with its own IP address assigned by the network, not by the splitter . In short, optical splitters enable efficient fiber sharing but do not interact with or split IP addresses.
